

Computational Intelligence

Winter Term 2021/22

Prof. Dr. Günter Rudolph

Lehrstuhl für Algorithm Engineering (LS 11)

Fakultät für Informatik

TU Dortmund

Plan for Today

Lecture 13

- Recurrent Neural Networks
 - Excursion: Nonlinear Dynamics
 - Recurrent Models
 - Training

Dynamical Systems with Discrete Time

Lecture 13

S state space with states $s \in S$

$s^{(t)}$ is a state $\in S$ at time $t \in \mathbb{N}_0$

Θ parameter space with parameters $\theta \in \Theta$

$f : S \times \Theta \rightarrow S$ transition function

→ dynamical system $s^{(t+1)} = f(s^{(t)}, \theta)$ (*) recurrence relation

$$s^{(t)} = f^t(s^{(0)}, \theta) = \underbrace{f \circ \dots \circ f}_{t \text{ times}}(s^{(0)}, \theta) = \underbrace{f_\theta(f_\theta(\dots f_\theta(s^{(0)}))))}_{t \text{ times}}; f_\theta(s) = f(s, \theta)$$

D: s^* is called **stationary point / fixed point / steady state of (*)** if $s^* = f(s^*)$

D: stationary point s^* is **locally asymptotically stable (l.a.s.)** if

$$\exists \varepsilon > 0 : \forall s^{(0)} \in B_\varepsilon(s^*) : \lim_{t \rightarrow \infty} s^{(t)} = s^*$$

T: Let f be differentiable. Then s is l.a.s. if $|f'(s)| < 1$, and unstable if $|f'(s)| > 1$.

Remark: D: $s \in S$ is **recurrent** if $\forall \varepsilon > 0 : \exists t > 0 : f^t(s) \in B_\varepsilon(s)$ infinitely often (i.o.)

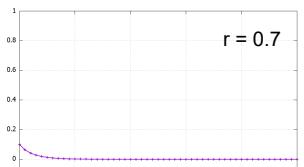

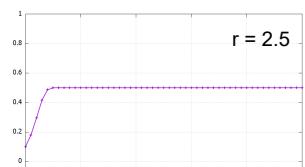

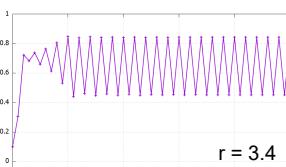

Dynamical Systems with Discrete Time

Lecture 13

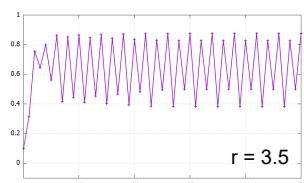

examples

- linear case: $f(x) = ax + b \quad a, b \in \mathbb{R}$
 - fixed points: $x = f(x) = ax + b \Rightarrow x = \frac{b}{1-a}$ if $a \neq 1$
 - stability: $f'(x) = a \Rightarrow |f'(x^*)| = |a| < 1$ l.a.s., $|a| > 1$ unstable
 - nonlinear case: $f(x) = rx(1-x) \quad r \in (0, 4] \quad x \in (0, 1)$ logistic map
 - fixed points: $x = f(x) = rx(1-x) \Rightarrow x = 0$ or $x = 1 - \frac{1}{r} = \frac{r-1}{r}$
 - stability: $f'(x) = r - 2rx$
 - $|f'(0)| = r < 1 \Rightarrow$ l.a.s. also for $r = 1$ since $x < f(x)$ for $x < \frac{1}{2}$
 - $|f'(\frac{r-1}{r})| = |2 - r| < 1 \Leftrightarrow 1 < r < 3$ l.a.s.
 - $r \in [3, 1 + \sqrt{6})$ oscillation between 2 values
 - $r \in [1 + \sqrt{6}, 3.54\dots)$ oscillation between 4 values
 - \vdots
 - $r > 3.56995\dots$ deterministic chaos
- predicting a nonlinear dynamic system may be impossible!

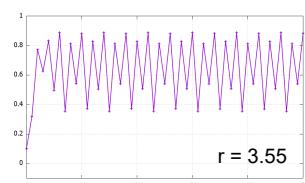

logistic map

starting at $x = 0.1$ stable fixed point at $x = 0$ stable fixed point at $x = 0.5$ 

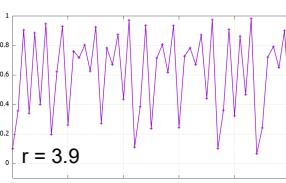

periodic orbit of size 2

periodic orbit of size 4

periodic orbit of size 8

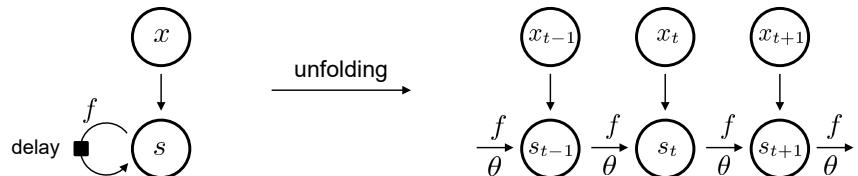

deterministic chaos

Recurrent Neural Networks (RNN)

unfolding

- finite input sequence
⇒ can unfold RNN completely to (deep) feed forward network
- infinite input sequence
⇒ can unfold RNN only finitely many steps into the past
⇒ assumption: behavior mainly depends on few inputs in the past
(i.e., **no** long-term dependencies)

remark: parameters θ in unfolded network are shared
otherwise with θ_t overfitting becomes very likely!

extensions

- dynamical system with inputs

$$s^{(t)} = f(s^{(t-1)}, x^{(t)}; \theta)$$

input at time $t \in \mathbb{N}$

- dynamical system with inputs and outputs

$$s^{(t)} = f(s^{(t-1)}, x^{(t)}; \theta_f)$$

$$o^{(t)} = g(s^{(t)}; \theta_g)$$

output at time $t \in \mathbb{N}$

describes a
recurrent
neural network
(RNN)

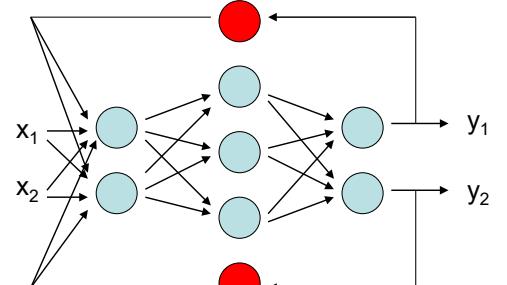

Historic Recurrent Neural Networks

- Jordan network (1983)

$$\begin{aligned} s_t &= f(s_{t-1}, x_t; W, U, b) \\ &= \sigma(Wx_t + U\hat{y}_{t-1} + b) \end{aligned}$$

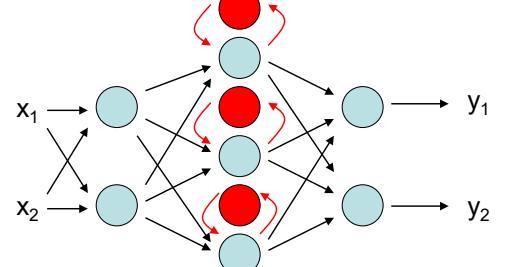

$$\begin{aligned} o_t &= g(s_t; V, c) \\ &= Vs_t + c \end{aligned}$$

$$\hat{y}_t = a(o_t)$$

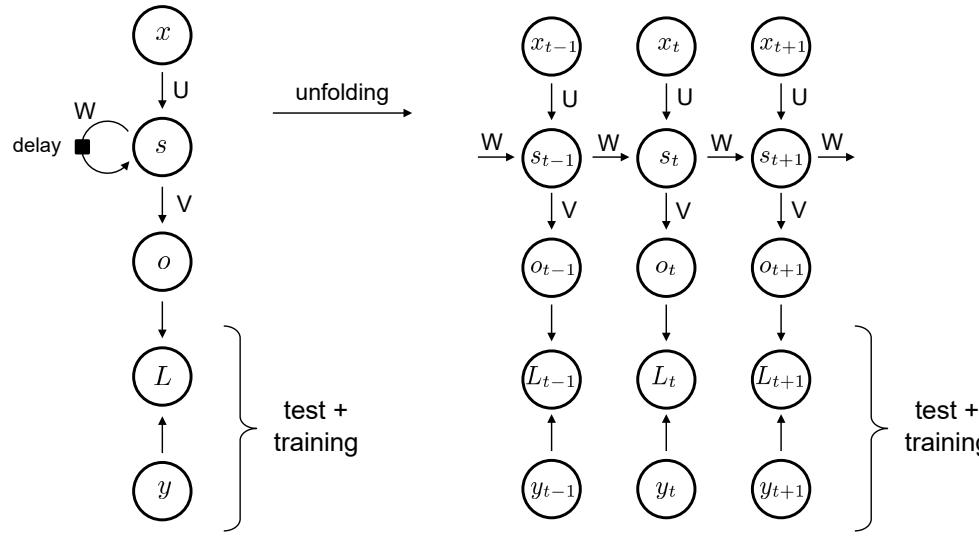

- Elman network (1990)

$$\begin{aligned} s_t &= \sigma(Wx_t + Us_{t-1} + b) \\ o_t &= Vs_t + c \\ \hat{y}_t &= a(o_t) \end{aligned}$$

test / training mode

loss per input $L(\hat{y}, y) = \|\hat{y} - y\|_2^2$ where $\hat{y} = \text{SOFTMAX}(o)$

training? → backpropagation through time (BPTT)

- works on unfolded network for a finite input sequence $x^{(1)}, \dots, x^{(\tau)}$
- some adaption to BP necessary, since many parameters are shared
 - ↑ reduces #params and overfitting
- “straightforward” (but tedious + error-prone if done manually)
 - use method from your software library!
- in principle: gradient descent on loss function

LSTM network (1997f.)

LSTM = long short-term memory

so far: no long-term dependencies

now: “remember the important stuff and forget the rest” [Cha18, p.89]

concept: two versions of the past

historic/standard RNN
forget too quickly

1. selective long-term memory
2. short term memory

- has the ability to learn long-term dependencies

LSTM Neuron

LSTM = long short-term memory
