Design of Evolutionary Algorithms

Lecture 08

Mutative Step Size Control

Individual $(\mathbf{x}, \boldsymbol{\theta}) \in \mathbb{Z}^n \times \mathbb{R}_+$

First, mutate step size

 $\theta_{t+1} = \theta_t \cdot L$

Second, mutate parent $Y = x + \theta_{t+1} \cdot Z$

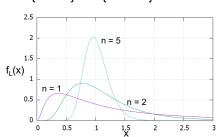

where L = $\exp(N)$ with N ~ N(0, 1/n)

Often: assure minimal step size ≥ 1

 $\theta_{t+1} = \max\{1, \theta_t \cdot L\}$

log-normal distributed

 $P\{L > c\} = P\{L < 1/c\} \text{ for } c \ge 1$

→ transferred: Rudolph (1994) for integer variables

→ invented: Schwefel (1977) for real variables

Lecture 08

ad 2) design guidelines for variation operators in practice

continuous search space $X = \mathbb{R}^n$

a) reachability → mutation distribution with unbounded support

b) unbiasedness — mutation distribution with maximum entropy

c) control → mutation distribution with parameters

⇒ leads to CMA-ES!

Covariance Matrix Adaptation

Towards CMA-ES

Lecture 08

mutation: Y = X + Z

 $Z \sim N(0, C)$ multinormal distribution

how should we choose covariance matrix C?

unless we have not learned something about the problem during search

 \Rightarrow don't prefer any direction!

 \Rightarrow covariance matrix C = I_n (unit matrix)

 $C = I_n$

 $C = diag(s_1,...,s_n)$

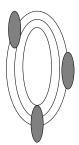

C orthogonal

Towards CMA-ES

Lecture 08

claim: mutations should be aligned to isolines of problem (Schwefel 1981)

if true then covariance matrix should be inverse of Hessian matrix!

$$\Rightarrow$$
 assume f(x) $\approx \frac{1}{2} x^4 A x + b^4 x + c \Rightarrow H = A$

$$Z \sim N(0, C)$$
 with density
$$f_Z(x) = \frac{1}{(2\pi)^{n/2} |C|^{1/2}} \exp\left(-\frac{1}{2}x'C^{-1}x\right)$$

since then many proposals how to adapt the covariance matrix

 \Rightarrow extreme case: use n+1 pairs (x, f(x)), apply multiple linear regression to obtain estimators for A, b, c invert estimated matrix A! OK, **but**: O(n⁶)! (Rudolph 1992)

principal axis

should point into negative gradient direction!

(proof next slide)

Lecture 08

most (effective) algorithms behave like this:

doubts: are equi-aligned isolines really optimal?

run roughly into negative gradient direction, sooner or later we approach longest main principal axis of Hessian,

now negative gradient direction coincidences with direction to optimum, which is parallel to longest main principal axis of Hessian, which is parallel to the longest main principal axis of the inverse covariance matrix

(Schwefel OK in this situation)

technische universität dortmund

G. Rudolph: Computational Intelligence • Winter Term 2024/25

Towards CMA-ES

Lecture 08

Apart from (inefficient) regression, how can we get matrix elements of Q?

 $C^{(k+1)}$ = update($C^{(k)}$, Population^(k)) ⇒ iteratively:

 $C^{(k)}$ must be positive definite (p.d.) and symmetric for all $k \ge 0$, basic constraint:

otherwise Cholesky decomposition impossible: C = Q'Q

Lemma

Let A and B be quadratic matrices and α , $\beta > 0$.

- a) A, B symmetric $\Rightarrow \alpha A + \beta B$ symmetric.
- b) A positive definite and B positive semidefinite $\Rightarrow \alpha A + \beta B$ positive definite

ad a) C = α A + β B symmetric, since $c_{ii} = \alpha a_{ii} + \beta b_{ii} = \alpha a_{ii} + \beta b_{ii} = c_{ii}$

ad b) $\forall x \in \mathbb{R}^n \setminus \{0\}$: $x'(\alpha A + \beta B) x = \alpha x'Ax + \beta x'Bx > 0$

Towards CMA-ES

Lecture 08

Theorem

A quadratic matrix $C^{(k)}$ is symmetric and positive definite for all $k \ge 0$, if it is built via the iterative formula $C^{(k+1)} = \alpha_k C^{(k)} + \beta_k v_k v'_k$ where $C^{(0)} = I_n$, $v_k \neq 0$, $\alpha_k > 0$ and liminf $\beta_k > 0$.

Proof:

If $v \neq 0$, then matrix V = vv' is symmetric and positive semidefinite, since

- as per definition of the dyadic product $v_{ii} = v_i \cdot v_i = v_i \cdot v_i = v_{ii}$ for all i, j and
- for all $x \in \mathbb{R}^n$: $x'(vv') x = (x'v) \cdot (v'x) = (x'v)^2 \ge 0$.

Thus, the sequence of matrices $v_k v_k'$ is symmetric and p.s.d. for $k \ge 0$.

Owing to the previous lemma matrix $C^{(k+1)}$ is symmetric and p.d., if $C^{(k)}$ is symmetric as well as p.d. and matrix $v_k v_k^{\prime}$ is symmetric and p.s.d.

Since $C^{(0)} = I_p$ symmetric and p.d. it follows that $C^{(1)}$ is symmetric and p.d. Repetition of these arguments leads to the statement of the theorem.

G. Rudolph: Computational Intelligence • Winter Term 2024/25

CMA-ES

Idea: Don't estimate matrix C in each iteration! Instead, approximate iteratively!

(Hansen, Ostermeier et al. 1996ff.)

→ Covariance Matrix Adaptation Evolutionary Algorithm (CMA-EA)

Set initial covariance matrix to $C^{(0)} = I_n$

$$C^{(t+1)} = (1-\eta) C^{(t)} + \eta \sum_{i=1}^{\mu} w_i (x_{i:\lambda} - m^{(t)}) (x_{i:\lambda} - m^{(t)})$$

$$\eta~$$
 : "learning rate" \in (0,1)

$$\text{w}_{\text{i}}$$
: weights; mostly $1/\mu$

Lecture 08

$$m = \frac{1}{\mu} \sum_{i=1}^{\mu} x_{i:\lambda}$$
 mean of all selected parents

complexity: $O(\mu n^2 + n^3)$

sorting: $f(x_{1\cdot\lambda}) \le f(x_{2\cdot\lambda}) \le ... \le f(x_{\lambda\cdot\lambda})$

Caution: must use mean m(t) of "old" selected parents; not "new" mean m(t+1)!

⇒ Seeking covariance matrix of fictitious distribution pointing in gradient direction!
