# Computational Intelligence 

## Winter Term 2010/11

Prof. Dr. Günter Rudolph
Lehrstuhl für Algorithm Engineering (LS 11)
Fakultät für Informatik
TU Dortmund

- Approximate Reasoning
- Fuzzy control

## Approximative Reasoning

## So far:

- p : IF $X$ is A THEN $Y$ is B
$\rightarrow R(x, y)=\operatorname{Imp}(A(x), B(y))$
rule as relation; fuzzy implication
- rule: $\quad$ IF $X$ is $A$ THEN $Y$ is $B$
fact: $\quad X$ is $A^{\prime}$
conclusion: $\quad Y$ is $B^{\prime}$
$\rightarrow B^{\prime}(y)=\sup _{x \in X} t\left(A^{\prime}(x), R(x, y)\right) \quad$ composition rule of inference

## Thus:

- $B^{\prime}(y)=\sup _{x \in X} t\left(A^{\prime}(x), \operatorname{Imp}(A(x), B(y))\right)$

## Approximative Reasoning

## Approximative Reasoning

Lemma:
a) $t(a, 1)=a$
b) $t(a, b) \leq \min \{a, b\}$
c) $t(0, a)=0$

## Proof:

ad a) Identical to axiom 1 of t-norms.
$a d b)$ From monotonicity (axiom 2) follows for $b \leq 1$, that $t(a, b) \leq t(a, 1)=a$.
Commutativity (axiom 3 ) and monotonicity lead in case of $a \leq 1$ to $t(a, b)=t(b, a) \leq t(b, 1)=b$. Thus, $t(a, b)$ is less than or equal to $a$ as well as $b$, which in turn implies $t(a, b) \leq \min \{a, b\}$.
$a d c$ ) From $b$ ) follows $0 \leq t(0, a) \leq \min \{0, a\}=0$ and therefore $t(0, a)=0$.

## Approximative Reasoning

## Multiple rules:

IF $X$ is $A_{1}$, THEN $Y$ is $B_{1}$
IF $X$ is $A_{2}$, THEN $Y$ is $B_{2}$
IF $X$ is $A_{3}$, THEN $Y$ is $B_{3}$
IF $X$ is $A_{n}$, THEN $Y$ is $B_{n}$ $X$ is $A^{\text {a }}$
$Y$ is $B^{\text {c }}$
$\rightarrow R_{1}(x, y)=\operatorname{Imp}_{1}\left(A_{1}(x), B_{1}(y)\right)$
$\rightarrow R_{2}(x, y)=\operatorname{lmp}_{2}\left(A_{2}(x), B_{2}(y)\right)$
$\rightarrow R_{3}(x, y)=\operatorname{Imp}_{3}\left(A_{3}(x), B_{3}(y)\right)$
$\rightarrow R_{n}(x, y)=\operatorname{Imp}_{n}\left(A_{n}(x), B_{n}(y)\right)$

Multiple rules for crisp input: $x_{0}$ is given

$$
\left.\begin{array}{l}
B_{1}{ }_{1}(y)=\operatorname{lmp}_{1}\left(A_{1}\left(x_{0}\right), B_{1}(y)\right) \\
\mathrm{B}_{n}^{\prime}(y)=\operatorname{lmp}_{n}\left(A_{n}\left(x_{0}\right), B_{n}(y)\right)
\end{array}\right\} \quad \begin{gathered}
\text { aggregation of rules or } \\
\text { local inferences necessary! }
\end{gathered}
$$

aggregate $!\Rightarrow B^{\prime}(y)=\operatorname{aggr}\left\{B_{1}(y), \ldots, B_{n}^{\prime}(y)\right\}$, where aggr $=\left\{\begin{array}{l}\min \\ \max \end{array}\right.$

## Approximative Reasoning

FITA: "First inference, then aggregate!"

1. Each rule of the form IF $X$ is $A_{k}$ THEN $Y$ is $B_{k}$ must be transformed by an appropriate fuzzy implication $\operatorname{Imp}_{k}(\cdot, \cdot)$ to a relation $R_{k}$ :
$R_{k}(x, y)=\operatorname{Imp}_{k}\left(A_{k}(x), B_{k}(y)\right)$.
2. Determine $B_{k}{ }^{\prime}(y)=R_{k}(x, y) \circ A^{\prime}(x)$ for all $k=1, \ldots, n$ (locale inference).
3. Aggregate to $B^{\prime}(y)=\beta\left(B_{1}{ }^{\prime}(y), \ldots, B_{n}{ }^{\prime}(y)\right)$.

FATI: "First aggregate, then inference!"

1. Each rule of the form IF $X$ ist $A_{k}$ THEN $Y$ ist $B_{k}$ must be transformed by an appropriate fuzzy implication $\operatorname{Imp}_{k}(\cdot, \cdot)$ to a relation $R_{k}$ : $R_{k}(x, y)=\operatorname{Imp}_{k}\left(A_{k}(x), B_{k}(y)\right)$.
2. Aggregate $R_{1}, \ldots, R_{n}$ to a superrelation with aggregating function $\alpha(\cdot)$ : $R(x, y)=\alpha\left(R_{1}(x, y), \ldots, R_{n}(x, y)\right)$.
3. Determine $B^{\prime}(y)=R(x, y) \circ A^{\prime}(x)$ w.r.t. superrelation (inference).

## Approximative Reasoning

1. Which principle is better? FITA or FATI?
2. Equivalence of FITA and FATI ?

FITA:

$$
\begin{aligned}
B^{\prime}(y) & =\beta\left(B_{1}^{\prime}(y), \ldots, B_{n}^{\prime}(y)\right) \\
& =\beta\left(R_{1}(x, y) \circ A^{\prime}(x), \ldots, R_{n}(x, y) \circ A^{\prime}(x)\right)
\end{aligned}
$$

FATI:

$$
\begin{aligned}
B^{\prime}(y) & =R(x, y) \circ A^{\prime}(x) \\
& =\alpha\left(R_{1}(x, y), \ldots, R_{n}(x, y)\right) \circ A^{\prime}(x)
\end{aligned}
$$

## Approximative Reasoning

special case:
$A^{\prime}(x)= \begin{cases}1 & \text { for } x=x_{0} \\ 0 & \text { otherwise }\end{cases}$ crisp input!

On the equivalence of FITA and FATI:
FITA:

$$
\begin{aligned}
B^{\prime}(y) & =\beta\left(B_{1}{ }^{\prime}(y), \ldots, B_{n}(y)\right) \\
& =\beta\left(\operatorname{lmp}_{1}\left(A_{1}\left(x_{0}\right), B_{1}(y)\right), \ldots, \operatorname{Imp}_{n}\left(A_{n}\left(x_{0}\right), B_{n}(y)\right)\right)
\end{aligned}
$$

FATI:

$$
\begin{aligned}
B^{\prime}(y) & =R(x, y) \circ A^{\prime}(x) \\
& =\sup _{x \in x} t\left(A^{\prime}(x), R(x, y)\right) \quad \text { (from now: special case) } \\
& =R\left(x_{0}, y\right) \\
& =\alpha\left(\operatorname{lmp}_{1}\left(A_{1}\left(x_{0}\right), B_{1}(y)\right), \ldots, \operatorname{lmp}_{n}\left(A_{n}\left(x_{0}\right), B_{n}(y)\right)\right)
\end{aligned}
$$

evidently: sup-t-composition with arbitrary t-norm and $\alpha(\cdot)=\beta(\cdot)$

## Approximative Reasoning

- AND-connected premises

IF $X_{1}=A_{11}$ AND $X_{2}=A_{12}$ AND $\ldots$ AND $X_{m}=A_{1 m}$ THEN $Y=B_{1}$
IF $X_{n}=A_{n 1}$ AND $X_{2}=A_{n 2}$ AND $\ldots$ AND $X_{m}=A_{n m}$ THEN $Y=B_{n}$
reduce to single premise for each rule k :
$A_{k}\left(x_{1}, \ldots, x_{m}\right)=\min \left\{A_{k 1}\left(x_{1}\right), A_{k 2}\left(x_{2}\right), \ldots, A_{k m}\left(x_{m}\right)\right\}$
or in general: t-norm

- OR-connected premises

IF $X_{1}=A_{11} O R X_{2}=A_{12} O R \ldots O R X_{m}=A_{1 m}$ THEN $Y=B_{1}$
IF $X_{n}=A_{n 1} O R X_{2}=A_{n 2}$ OR $\ldots$ OR $X_{m}=A_{n m}$ THEN $Y=B_{n}$
reduce to single premise for each rule $k$ :
$A_{k}\left(x_{1}, \ldots, x_{m}\right)=\max \left\{A_{k 1}\left(x_{1}\right), A_{k 2}\left(x_{2}\right), \ldots, A_{k m}\left(x_{m}\right)\right\}$
or in general: s-norm
important:

- if rules of the form IF $X$ is A THEN $Y$ is $\mathbf{B}$ interpreted as logical implication
$\Rightarrow R(x, y)=\operatorname{Imp}(A(x), B(y))$ makes sense
- we obtain: $B^{\prime}(y)=\sup _{x \in \mathrm{X}} t\left(A^{\prime}(x), R(x, y)\right)$
$\Rightarrow$ the worse the match of premise $A^{\prime}(x)$, the larger is the fuzzy set $B^{\prime}(y)$
$\Rightarrow$ follows immediately from axiom 1: $\mathrm{a} \leq \mathrm{b}$ implies $\operatorname{Imp}(\mathrm{a}, \mathrm{z}) \geq \operatorname{Imp}(\mathrm{b}, \mathrm{z})$
interpretation of output set $B^{\prime}(y)$ :
- $B^{\prime}(y)$ is the set of values that are still possible
- each rule leads to an additional restriction of the values that are still possible
$\Rightarrow$ resulting fuzzy sets $B_{k}^{\prime}(y)$ obtained from single rules must be mutually intersected!
$\Rightarrow$ aggregation via $B^{\prime}(y)=\boldsymbol{\operatorname { m i n }}\left\{B_{1}{ }^{\prime}(y), \ldots, B_{n}{ }^{\prime}(y)\right\}$

## Approximative Reasoning

important:

- if rules of the form IF $X$ is A THEN $Y$ is $\mathbf{B}$ are not interpreted as logical implications, then the function $\operatorname{Fct}(\cdot)$ in

$$
R(x, y)=F c t(A(x), B(y))
$$

can be chosen as required for desired interpretation.

- frequent choice (especially in fuzzy control):
$-R(x, y)=\min \{A(x), B(x)\}$
Mamdami - "implication"
$-R(x, y)=A(x) \cdot B(x) \quad$ Larsen - "implication"
$\Rightarrow$ of course, they are no implications but special t-norms!
$\Rightarrow$ thus, if relation $R(x, y)$ is given, then the composition rule of inference

$$
B^{\prime}(y)=A^{\prime}(x) \circ R(x, y)=\sup _{x \in x} \min \left\{A^{\prime}(x), R(x, y)\right\}
$$

still can lead to a conclusion via fuzzy logic.

## Approximative Reasoning

example: [JM96, S. 244ff.]
industrial drill machine $\rightarrow$ control of cooling supply
modelling
linguistic variable
linguistic terms
ground set $: \mathcal{X}$ with $0 \leq x \leq 18000$ [rpm]
: rotation speed
: very low, low, medium, high, very high

## Approximative Reasoning

example: (continued)
industrial drill machine $\rightarrow$ control of cooling supply
modelling
linguistic variable
linguistic terms
ground set
: cooling quantity
: very small, small, normal, much, very much
$: \mathcal{Y}$ with $0 \leq y \leq 18$ [liter / time unit]
cocling

## Approximative Reasoning

## Lecture 08

example: (continued)
industrial drill machine $\rightarrow$ control of cooling supply
rule base
IF rotation speed IS very low THEN cooling quantity IS very small

| low | small |
| :--- | :--- |
| medium | normal |
| high | much |
| very high | very much |

sets $S_{v l}, S_{l}, S_{m}, S_{h}, S_{v h}$
"rotation speed"
sets $\mathrm{C}_{\mathrm{vs}}, \mathrm{C}_{\mathrm{s}}, \mathrm{C}_{\mathrm{n}}, \mathrm{C}_{\mathrm{m}}, \mathrm{C}_{\mathrm{vm}}$
"cooling quantity"

## Approximative Reasoning

example: (continued)
industrial drill machine $\rightarrow$ control of cooling supply

1. input: crisp value $x_{0}=10000 \mathrm{~min}^{-1}$ (no fuzzy set!)
$\rightarrow$ fuzzyfication $=$ determine membership for each fuzzy set over $\mathcal{X}$
$\rightarrow$ yields $S^{\prime}=(0,0,3 / 4,1 / 4,0)$ via $\mathrm{x} \mapsto\left(\mathrm{S}_{\mathrm{v} 1}\left(\mathrm{x}_{0}\right), \mathrm{S}_{\mathrm{l}}\left(\mathrm{x}_{0}\right), \mathrm{S}_{\mathrm{m}}\left(\mathrm{x}_{0}\right), \mathrm{S}_{\mathrm{h}}\left(\mathrm{x}_{0}\right), \mathrm{S}_{\mathrm{vh}}\left(\mathrm{x}_{0}\right)\right)$
2. FITA: locale inference $\Rightarrow$ since $\operatorname{Imp}(0, a)=0$ we only need to consider:
$S_{m}: \quad C_{n}^{\prime}(y)=\operatorname{Imp}\left(3 / 4, C_{n}(y)\right)$
$S_{h}: \quad C_{m}^{\prime}(y)=\operatorname{Imp}\left(1 / 4, C_{m}(y)\right)$
3. aggregation:
$\left.C^{\prime}(y)=\operatorname{aggr}\left\{C_{n}^{\prime}(y), C_{m}^{\prime}(y)\right\}=\max \left\{\left(1 / 4, C_{n}(y)\right), 1 \operatorname{Imp}^{1 / 4}, C_{m}(y)\right)\right\}$

## Approximative Reasoning

example: (continued)
industrial drill machine $\rightarrow$ control of cooling supply
$C^{\prime}(y)=\max \left\{\operatorname{Imp}\left(3 / 4, C_{n}(y)\right), \operatorname{Imp}\left(1 / 4, C_{m}(y)\right)\right\}$
in case of control task typically no logic-based interpretation:
$\rightarrow$ max-aggregation and
$\rightarrow$ relation $R(x, y)$ not interpreted as implication.
often: $R(x, y)=\min (a, b) \quad$ "Mamdani controller"
thus:
$C^{\prime}(y)=\max \left\{\min \left\{3 / 4, C_{n}(y)\right\}, \min \left\{1 / 4, C_{m}(y)\right\}\right\}$
$\rightarrow$ graphical illustration

## Approximative Reasoning

example: (continued)
industrial drill machine $\rightarrow$ control of cooling supply
$C^{\prime}(y)=\max \left\{\min \left\{3 / 4, C_{n}(y)\right\}, \min \left\{1 / 4, C_{m}(y)\right\}\right\}, x_{0}=10000[r p m]$

## open and closed loop control:

affect the dynamical behavior of a system
in a desired manner

- open loop control
control is aware of reference values and has a model of the system
$\Rightarrow$ control values can be adjusted, such that process value of system is equal to reference value
problem: noise! $\Rightarrow$ deviation from reference value not detected
- closed loop control
now: detection of deviations from reference value possible (by means of measurements / sensors) and new control values can take into account the amount of deviation

## Fuzzy Control

## open loop control

assumption: undisturbed operation $\Rightarrow$ process value $=$ reference value

## Fuzzy Control

## closed loop control

control deviation $=$ reference value - process value

## required:

model of system / process
$\rightarrow$ as differential equations or difference equations (DEs)
$\rightarrow$ well developed theory available

## so, why fuzzy control?

- there exists no process model in form of DEs etc. (operator/human being has realized control by hand)
- process with high-dimensional nonlinearities $\rightarrow$ no classic methods available
- control goals are vaguely formulated („soft" changing gears in cars)

## Fuzzy Control

## fuzzy description of control behavior

IF $X$ is $A_{1}$, THEN $Y$ is $B_{1}$
IF $X$ is $A_{2}$, THEN $Y$ is $B_{2}$
IF $X$ is $A_{3}$, THEN $Y$ is $B_{3}$
IF $X$ is $A_{n}$, THEN $Y$ is $B_{n}$ $X$ is $A^{\cdot}$
$Y$ is $B^{\text {c }}$
similar to approximative reasoning
but fact $A^{\prime}$ is not a fuzzy set but a crisp input
$\rightarrow$ actually, it is the current process value
fuzzy controller executes inference step
$\rightarrow$ yields fuzzy output set $B^{\prime}(y)$
but crisp control value required for the process / system
$\rightarrow$ defuzzification (= "condense" fuzzy set to crisp value)

## defuzzification

Def: rule k active $\Leftrightarrow \mathrm{A}_{k}\left(\mathrm{x}_{0}\right)>0$

- maximum method
- only active rule with largest activation level is taken into account
$\rightarrow$ suitable for pattern recognition / classification
$\rightarrow$ decision for a single alternative among finitely many alternatives
- selection independent from activation level of rule ( 0.05 vs .0 .95 )
- if used for control: incontinuous curve of output values (leaps)

## defuzzification

$$
Y^{*}=\left\{y \in Y^{\prime} B^{\prime}(y)=\operatorname{hgt}\left(B^{\prime}\right)\right\}
$$

- maximum mean value method
- all active rules with largest activation level are taken into account
$\rightarrow$ interpolations possible, but need not be useful
$\rightarrow$ obviously, only useful for neighboring rules with max. activation
- selection independent from activation level of rule ( 0.05 vs .0 .95 )
- if used in control: incontinuous curve of output values (leaps)

$$
\check{y}=\frac{1}{\left|Y^{*}\right|} \sum_{y^{*} \in Y^{*}} y^{*}
$$

## defuzzification

$$
Y^{*}=\left\{y \in Y^{\prime} B^{\prime}(y)=\operatorname{hgt}\left(B^{\prime}\right)\right\}
$$

- center-of-maxima method (COM)
- only extreme active rules with largest activation level are taken into account
$\rightarrow$ interpolations possible, but need not be useful
$\rightarrow$ obviously, only useful for neighboring rules with max. activation level
- selection indepependent from activation level of rule ( 0.05 vs .0 .95 )
- in case of control: incontinuous curve of output values (leaps)

$$
\bar{y}=\frac{\inf Y^{*}+\sup Y^{*}}{2}
$$

## Fuzzy Control

## defuzzification

- Center of Gravity (COG)
- all active rules are taken into account
$\rightarrow$ but numerically expensive ... ...only valid for HW solution, today!
$\rightarrow$ borders cannot appear in output ( $\exists$ work-around )
- if only single active rule: independent from activation level
- continuous curve for output values

$$
\bar{y}=\frac{\int y \cdot B^{\prime}(y) d y}{\int B^{\prime}(y) d y}
$$

Excursion: COG

$$
\check{y}=\frac{\int y \cdot B^{\prime}(y) d y}{\int B^{\prime}(y) d y}
$$

pendant in probability theory: expectation value
triangle:

trapezoid:

## Fuzzy Control

assumption: fuzzy membership functions piecewise linear
output set $B^{\prime}(y)$ represented by sequence of points $\left(y_{1}, z_{1}\right),\left(y_{2}, z_{2}\right), \ldots,\left(y_{n}, z_{n}\right)$
$\Rightarrow$ area under $\mathrm{B}^{\prime}(\mathrm{y})$ and weighted area can be determined additively piece by piece
$\Rightarrow$ linear equation $\mathrm{z}=\mathrm{my}+\mathrm{b} \Rightarrow \operatorname{insert}\left(\mathrm{y}_{\mathrm{i}}, \mathrm{z}_{\mathrm{i}}\right)$ and $\left(\mathrm{y}_{\mathrm{i}+1}, \mathrm{z}_{\mathrm{i}+1}\right)$
$\Rightarrow$ yields m and b for each of the $\mathrm{n}-1$ linear sections
$\Rightarrow F_{i}=\int_{y_{i}}^{y_{i+1}}(m y+b) d y=\frac{m}{2}\left(y_{i+1}^{2}-y_{i}^{2}\right)+b\left(y_{i+1}-y_{i}\right)$
$\Rightarrow G_{i}=\int_{y_{i}}^{y_{i+1}} y(m y+b) d y=\frac{m}{3}\left(y_{i+1}^{3}-y_{i}^{3}\right)+\frac{b}{2}\left(y_{i+1}^{2}-y_{i}^{2}\right)$
$\check{y}=\frac{\sum_{i} G_{i}}{\sum_{i} F_{i}}$

## Fuzzy Control

## Defuzzification

- Center of Area (COA)
- developed as an approximation of COG
- let $\hat{y}_{k}$ be the COGs of the output sets $\mathrm{B}_{\mathrm{k}}^{\prime}(\mathrm{y})$ :

$$
\check{y}=\frac{\sum_{k} A_{k}\left(x_{0}\right) \cdot \widehat{y}_{k}}{\sum_{k} A_{k}\left(x_{0}\right)}
$$
