# Computational Intelligence 

## Winter Term 2010/11

Prof. Dr. Günter Rudolph

Lehrstuhl für Algorithm Engineering (LS 11)
Fakultät für Informatik
TU Dortmund

## Swarm Intelligence

## Contents

- Ant algorithms
- Particle swarm algorithms
(combinatorial optimization)
(optimization in $\mathbb{R}^{n}$ )

## Swarm Intelligence

swarms of bird or fish
seeking for food

## concepts:

- evaluation of own current situation
- comparison with other conspecific
- imitation of behavior of successful conspecifics
$\Rightarrow$ audio-visual communication
dortmund

## Swarm Intelligence

## ant algorithms (ACO: Ant Colony Optimization)

paradigm for design of metaheuristics for combinatorial optimization
stigmergy $=$ indirect communication through modification of environment
~ 1991 Colorni / Dorigo / Maniezzo: Ant System (also: 1. ECAL, Paris 1991)
Dorigo (1992): collective behavor of social insects (PhD)
some facts:

- about $2 \%$ of all insects are social
- about $50 \%$ of all social insects are ants
- total weight of all ants = total weight of all humans
- ants populate earth since 100 millions years
- humans populate earth since 50.000 years
double bridge experiment (Deneubourg et al. 1990, Goss et al. 1989)

finally: all ants use the shorter bridge!

## How does it work?

- ants place pheromons on their way
- routing depends on concentration of pheromons

## more detailed:

ants that use shorter bridge return faster
$\Rightarrow$ pheromone concentration higher on shorter bridge
$\Rightarrow$ ants choose shorter bridge more frequently than longer bridge
$\Rightarrow$ pheromon concentration on shorter bridge even higher
positive feedback loop
$\Rightarrow$ even more ants choose shorter bridge
$\Rightarrow$ a.s.f.

## Swarm Intelligence

## Ant System (AS) 1991

combinatorial problem:

- components $\mathrm{C}=\left\{\mathrm{c}_{1}, \mathrm{c}_{2}, \ldots, \mathrm{c}_{\mathrm{n}}\right\}$
- feasible set $F \subseteq 2^{C}$
- objective function f: $2^{\mathrm{C}} \rightarrow \mathbb{R}$
ants $=$ set of concurrent (or parallel) asynchronous agents move through state of problems

partial solutions of problems
$\Rightarrow$ caused by movement of ants the final solution is compiled incrementally

## Swarm Intelligence

movement: stochastic local decision
(2 parameters)

while constructing the solution (if possible), otherwise at the end:

1. evaluation of solutions
2. modification of 'trail value' of components on the path
feedback

## Swarm Intelligence

## ant $\mathbf{k}$ in state $\mathbf{i}$

- determine all possible continuations of current state i
- choice of continuation according to probability distribution $\mathrm{p}_{\mathrm{ij}}$

$$
\mathrm{p}_{\mathrm{ij}}=\mathrm{q}(\text { attractivity, amount of pheromone })
$$

heuristic is based on a priori desirability of the move

a posteriori desirability of the move „how rewarding was the move in the past?"

- update of pheromone amount on the paths:
as soon as all ants have compiled their solutions good solution $\nearrow$ increase amount of pheromone, otherwise decrease

## Combinatorial Problems (Example TSP)

## TSP:

- ant starts in arbitrary city i
- pheromone on edges ( $\mathrm{i}, \mathrm{j}$ ): $\tau_{\mathrm{ij}}$
- probability to move from i to j: $\quad p_{i j}^{(t)}=\frac{\tau_{i j}^{\alpha} \eta_{i j}^{\beta}}{\sum_{k \in \mathcal{N}_{i}(t)} \tau_{i k}^{\alpha} \eta_{i k}^{\beta}} \quad$ for $j \in \mathcal{N}_{i}(t)$
- $\eta_{\mathrm{ij}}=1 / \mathrm{d}_{\mathrm{ij}} ; \mathrm{d}_{\mathrm{ij}}=$ distance between city i and j
- $\alpha=1$ and $\beta \in[2,5]$ (empirical), $\rho \in(0,1)$ "evaporation rate"
- $\mathcal{N}_{\mathrm{i}}(\mathrm{t})=$ neighborhood of i at time step t (without cities already visited)
- update of pheromone after $\mu$ journeys of ants: $\quad \tau_{i j}:=\rho \tau_{i j}+\sum_{k=1}^{\mu} \Delta \tau_{i j}(k)$
- $\Delta \tau_{\mathrm{ij}}(\mathrm{k})=1$ / (tour length of ant k ), if ( $\left.\mathrm{i}, \mathrm{j}\right)$ belongs to tour

## Swarm Intelligence

## two additional mechanisms:

1. trail evaporation
2. demon actions (for centralized actions; not executable in general)

Ant System (AS) is prototype
tested on TSP-Benchmark $\rightarrow$ not competitive
$\Rightarrow$ but: works in principle!
subsequent: 2 targets

1. increase efficiency ( $\rightarrow$ competitiveness with state-of-the-art method)
2. better explanation of behavior

1995 ANT-Q (Gambardella \& Dorigo), simplified: 1996 ACS ant colony system

## Particle Swarm Optimization (PSO)

paradigm for design of metaheuristics for continuous optimization
developed by Russel Eberhard \& James Kennedy (~1995)

## concepts:

- particle ( $\mathrm{x}, \mathrm{v}$ ) consists of position $\mathrm{x} \in \mathbb{R}^{\mathrm{n}}$ and "velocity" (i.e. direction) $\mathrm{v} \in \mathbb{R}^{\mathrm{n}}$
- PSO maintains multiple potential solutions at one time
- during each iteration, each solution/position is evaluated by an objective function
- particles "fly" or "swarm" through the search space
to find position of an extremal value returned by the objective function

## Swarm Intelligence

## PSO update of particle $\left(x_{i}, v_{i}\right)$ at iteration $t$

1st step:
$v_{i}(t+1)=\omega v_{i}(t)+\gamma_{1} R_{1}\left(x_{b}^{*}(t)-x_{i}(t)\right)+\gamma_{2} R_{2}\left(x^{*}(t)-x_{i}(t)\right)$

## Swarm Intelligence

## PSO update of particle $\left(x_{i}, v_{i}\right)$ at iteration $t$

1st step:
$v_{i}(t+1)=\omega v_{i}(t)+\gamma_{1} R_{1}\left(x_{b}^{*}(t)-x_{i}(t)\right)+\gamma_{2} R_{2}\left(x^{*}(t)-x_{i}(t)\right)$

new
direction

old direction

direction from
$x_{i}(t)$ to $x_{b}^{*}(t)$

direction from $x_{i}(t)$ to $x^{*}(t)$
$\omega \quad: \quad$ inertia factor, often $\in[0.8,1.2]$
$\gamma_{1}:$ cognitive factor, often $\in[1.7,2.0]$
$\gamma_{2}$ : social factor, often $\in[1.7,2.0]$
$R_{1}$ : positive r.v., often $r_{1} \sim U[0,1]$
$R_{2}$ : positive r.v., often $r_{2} \sim U[0,1]$

## Swarm Intelligence

## PSO update of particle $\left(x_{i}, v_{i}\right)$ at iteration $t$

2nd step:

$\underbrace{x_{i}(t+1)}_{$|  new  |
| :---: |
|  position  |$}=\underbrace{x_{i}(t)}_{$|  old  |
| :---: |
|  position  |
|  direction  |$}+\underbrace{v_{i}(t+1)}$

Note the similarity to the concept of mutative step size control in EAs: first change the step size (direction), then use changed step size (direction) for changing position.
