

Computational Intelligence

Winter Term 2021/22

Prof. Dr. Günter Rudolph

Lehrstuhl für Algorithm Engineering (LS 11)

Fakultät für Informatik

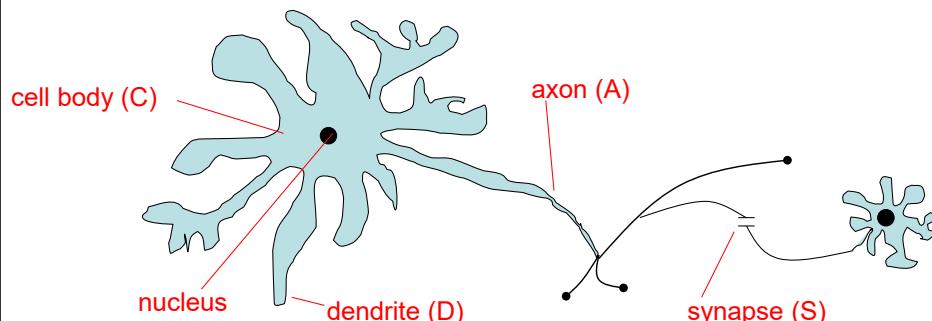

TU Dortmund

- Introduction to Artificial Neural Networks
 - McCulloch Pitts Neuron (MCP)
 - Minsky / Papert Perceptron (MPP)

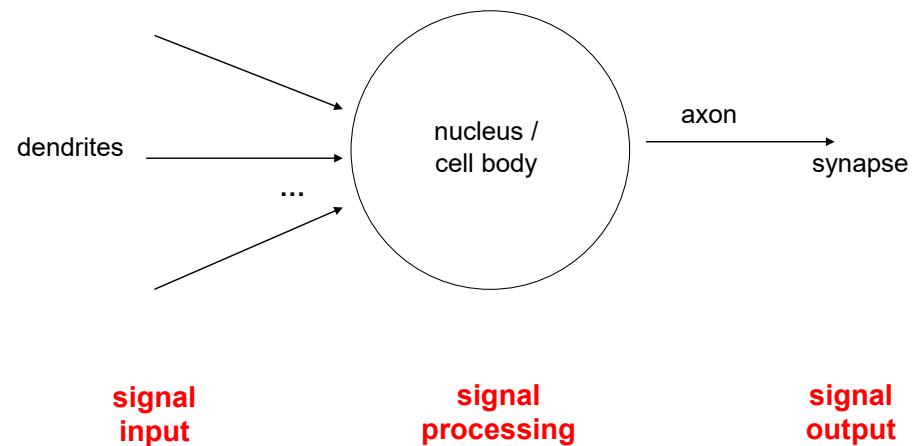

Biological Prototype

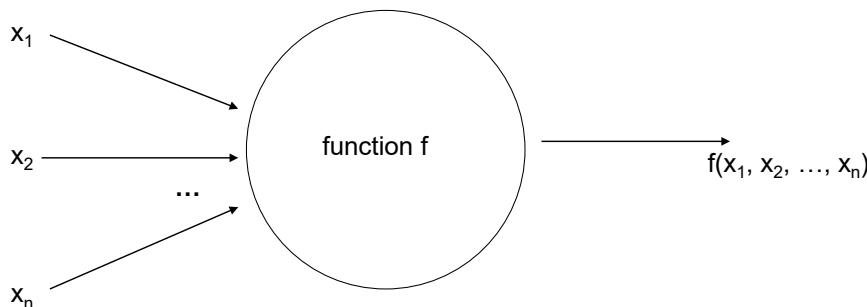

- Neuron
 - Information gathering (D)
 - Information processing (C)
 - Information propagation (A / S)

human being: 10^{12} neurons
electricity in mV range
speed: 120 m / s

Abstraction

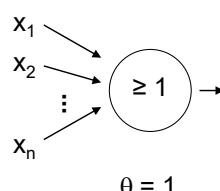

Model**McCulloch-Pitts-Neuron**

n binary input signals x_1, \dots, x_n

threshold $\theta > 0$

$$f(x_1, \dots, x_n) = \begin{cases} 1 & \text{if } \sum_{i=1}^n x_i \geq \theta \\ 0 & \text{else} \end{cases}$$

⇒ can be realized:
boolean OR

boolean AND

$\theta = n$

1943: Warren McCulloch / Walter Pitts

- description of neurological networks
→ modell: McCulloch-Pitts-Neuron (MCP)

- basic idea:
 - neuron is either active or inactive
 - skills result from **connecting** neurons

- considered static networks
(i.e. connections had been constructed and not learnt)

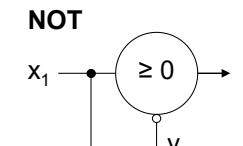

McCulloch-Pitts-Neuron

n binary input signals x_1, \dots, x_n

threshold $\theta > 0$

in addition: m binary inhibitory signals y_1, \dots, y_m

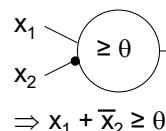

$$\tilde{f}(x_1, \dots, x_n; y_1, \dots, y_m) = f(x_1, \dots, x_n) \cdot \prod_{j=1}^m (1 - y_j)$$

- if at least one $y_j = 1$, then output = 0
- otherwise:
 - sum of inputs \geq threshold, then output = 1
 - else output = 0

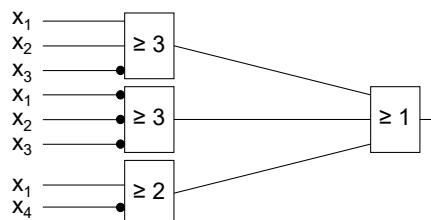

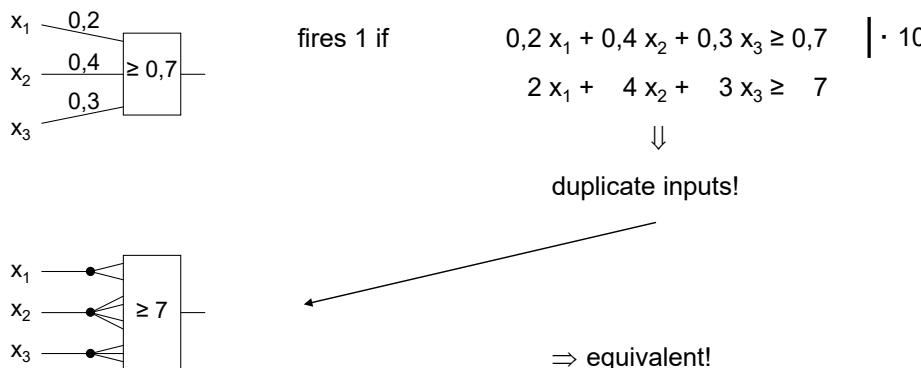

Assumption:

inputs also available in inverted form, i.e. \exists inverted inputs.

**Theorem:**

Every logical function $F: B^n \rightarrow B$ can be simulated with a two-layered McCulloch/Pitts net.

Example: $F(x) = x_1 x_2 \bar{x}_3 \vee \bar{x}_1 \bar{x}_2 \bar{x}_3 \vee x_1 \bar{x}_4$

**Generalization:** inputs with weights**Proof:** (by construction)

Every boolean function F can be transformed in disjunctive normal form
 \Rightarrow 2 layers (AND - OR)

1. Every clause gets a decoding neuron with $\theta = n$
 \Rightarrow output = 1 only if clause satisfied (AND gate)
2. All outputs of decoding neurons
 are inputs of a neuron with $\theta = 1$ (OR gate)

q.e.d.

Theorem:

Weighted and unweighted MCP-nets are equivalent for weights $\in \mathbb{Q}^+$.

Proof:

\Rightarrow Let $\sum_{i=1}^n \frac{a_i}{b_i} x_i \geq \frac{a_0}{b_0}$ with $a_i, b_i \in \mathbb{N}$

Multiplication with $\prod_{i=0}^n b_i$ yields inequality with coefficients in \mathbb{N}

Duplicate input x_i , such that we get $a_1 b_1 b_2 \dots b_{i-1} b_{i+1} \dots b_n$ inputs.

Threshold $\theta = a_0 b_1 \dots b_n$

\Leftarrow

Set all weights to 1.

q.e.d.

Conclusion for MCP nets:

- + feed-forward: able to compute any Boolean function
- + recursive: able to simulate DFA (deterministic finite automaton)
- very similar to conventional logical circuits
- difficult to construct
- no good learning algorithm available

Perceptron (Rosenblatt 1958)

- complex model → reduced by Minsky & Papert to what is „necessary“
- Minsky-Papert perceptron (MPP), 1969 → essential difference: $x \in [0,1] \subset \mathbb{R}$

What can a single MPP do?

$$w_1 x_1 + w_2 x_2 \geq \theta$$

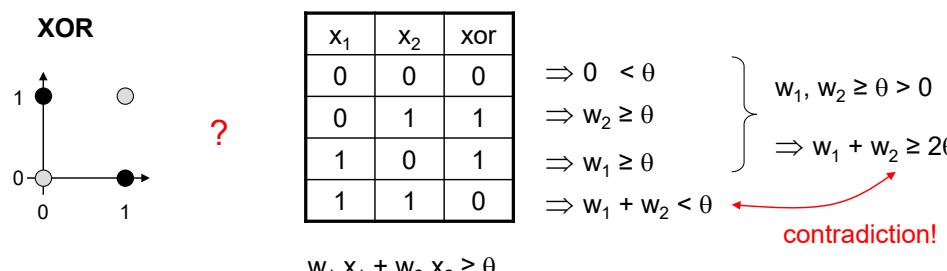

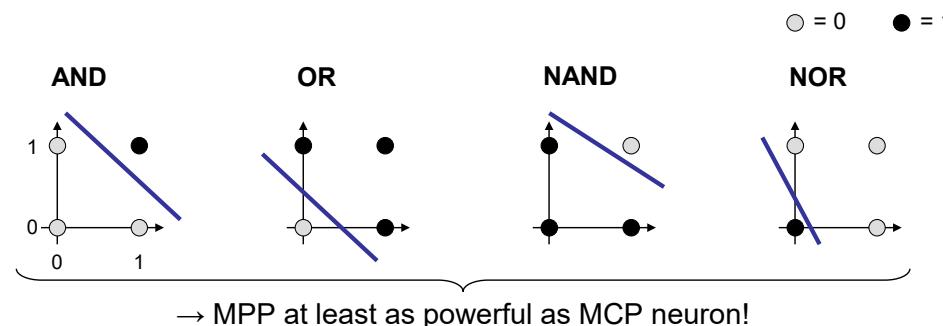

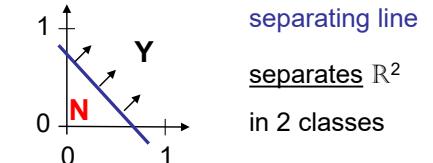

isolation of x_2 yields:

$$x_2 \geq \frac{\theta}{w_2} - \frac{w_1}{w_2} x_1$$

Example:

$$0,9 x_1 + 0,8 x_2 \geq 0,6$$

$$\Leftrightarrow x_2 \geq \frac{3}{4} - \frac{9}{8} x_1$$

**1969: Marvin Minsky / Seymour Papert**

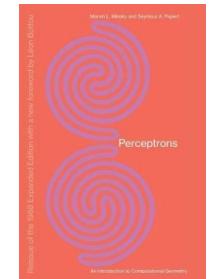

- book *Perceptrons* → analysis math. properties of perceptrons

disillusioning result:**perceptions fail to solve a number of trivial problems!**

- XOR Problem
- Parity Problem
- Connectivity Problem

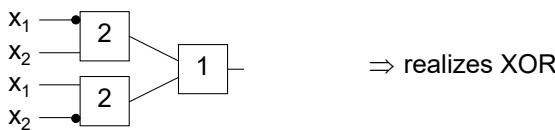

- “conclusion”: all artificial neurons have this kind of weakness!
⇒ research in this field is a scientific dead end!

- consequence: research funding for ANN cut down extremely (~ 15 years)

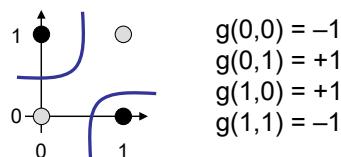

how to leave the „dead end“:

1. Multilayer Perceptrons:

2. Nonlinear separating functions:

$$\text{XOR} \quad g(x_1, x_2) = 2x_1 + 2x_2 - 4x_1x_2 - 1 \quad \text{with} \quad \theta = 0$$

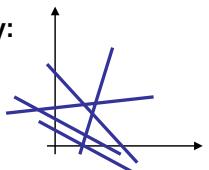

Perceptron Learning

Assumption: test examples with correct I/O behavior available

Principle:

- (1) choose initial weights in arbitrary manner
- (2) feed in test pattern
- (3) if output of perceptron wrong, then change weights
- (4) goto (2) until correct output for all test patterns

graphically:

→ translation and rotation of separating lines

How to obtain weights w_i and threshold θ ?

as yet: by construction

example: NAND-gate

x_1	x_2	NAND
0	0	1
0	1	1
1	0	1
1	1	0

$$\begin{aligned} &\Rightarrow 0 \geq \theta \\ &\Rightarrow w_2 \geq \theta \\ &\Rightarrow w_1 \geq \theta \\ &\Rightarrow w_1 + w_2 < \theta \end{aligned}$$

} requires solution of a system of linear inequalities ($\in P$)
(e.g.: $w_1 = w_2 = -2, \theta = -3$)

now: by „learning“ / training

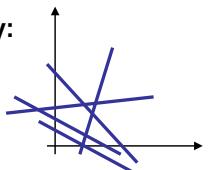

Perceptron Learning

Assumption: test examples with correct I/O behavior available

Principle:

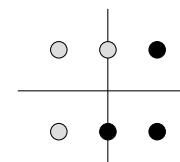

- (1) choose initial weights in arbitrary manner
- (2) feed in test pattern
- (3) if output of perceptron wrong, then change weights
- (4) goto (2) until correct output for all test patterns

graphically:

→ translation and rotation of separating lines

Example

$$P = \left\{ \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ -1 \end{pmatrix}, \begin{pmatrix} 0 \\ -1 \end{pmatrix} \right\}$$

$$N = \left\{ \begin{pmatrix} -1 \\ -1 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\}$$

threshold as a weight: $w = (\theta, w_1, w_2)'$

↓

$$P = \left\{ \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \\ -1 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \right\}$$

$$N = \left\{ \begin{pmatrix} -1 \\ -1 \\ -1 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \right\}$$

$$\begin{array}{l} \frac{-\theta}{w_1} \leq x_1 \\ \frac{-\theta}{w_2} \leq x_2 \end{array} \geq 0 \Leftrightarrow w_1x_1 + w_2x_2 - \theta \geq 0$$

$w_0 \quad x_0$

⇒ separating hyperplane:

$$H(w) = \{x : h(x; w) = 0\}$$

where

$$h(x; w) = w'x = w_0x_0 + w_1x_1 + \dots + w_nx_n$$

⇒ origin $0 \in H(w)$ since $h(0; w) = 0$

Perceptron Learning

1. choose w_0 at random, $t = 0$
2. choose arbitrary $x \in P \cup N$
3. if $x \in P$ and $w_t'x > 0$ then **goto 2**
if $x \in N$ and $w_t'x \leq 0$ then **goto 2**
4. if $x \in P$ and $w_t'x \leq 0$ then
 $w_{t+1} = w_t + x$; $t++$; **goto 2**
5. if $x \in N$ and $w_t'x > 0$ then
 $w_{t+1} = w_t - x$; $t++$; **goto 2**
6. stop? If I/O correct for all examples!

remark: if separating $H(w^*)$ exists, then algorithm converges, is finite (but in worst case: exponential runtime)

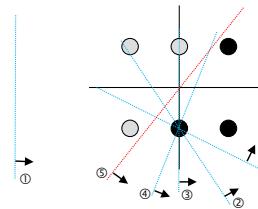

P: set of positive examples
N: set of negative examples
threshold θ integrated in weights

→ output 1
→ output 0

I/O correct!

let $w'x \leq 0$, should be > 0 !
 $(w+x)'x = w'x + x'x > w'x$

let $w'x > 0$, should be ≤ 0 !
 $(w-x)'x = w'x - x'x < w'x$

Example

suppose initial vector of weights is

$$w^{(0)} = (1, \frac{1}{2}, 1)'$$

```
> w = SPL(m,c(1,0.5,1))
[1] 1.0 0.5 1.0
[1] 2.0 0.5 0.0
[1] 1.0 1.5 1.0
[1] 0.0 2.5 0.0
[1] -1.0 2.5 -1.0
[1] 0.0 2.5 -2.0
```

Single-Layer Perceptron (SLP)**Acceleration of Perceptron Learning**

Assumption: $x \in \{0, 1\}^n \Rightarrow \|x\| = \sum_{i=1}^n |x_i| \geq 1$ for all $x \neq (0, \dots, 0)'$

Let $B = P \cup \{-x : x \in N\}$ (only positive examples)

If classification incorrect, then $w'x < 0$.

Consequently, size of error is just $\delta = -w'x > 0$.

$\Rightarrow w_{t+1} = w_t + (\delta + \varepsilon)x$ for $\varepsilon > 0$ (small) corrects error in a single step, since

$$\begin{aligned} w'_{t+1}x &= (w_t + (\delta + \varepsilon)x)'x \\ &= \underbrace{w'_t x}_{\geq 0} + (\delta + \varepsilon)x'x \\ &= -\delta + \delta \|x\|^2 + \varepsilon \|x\|^2 \\ &= \delta (\|x\|^2 - 1) + \varepsilon \|x\|^2 > 0 \quad \checkmark \\ &\quad \underbrace{\geq 0}_{> 0} \end{aligned}$$

SPL <- function(m,w) {

```
print(w)
repeat {
  OK <- TRUE
  for (i in 1:nrow(m)) {
    x <- m[i,]
    s <- x[1]*w[1]+x[2]*w[2]+x[3]*w[3]
    if (s <= 0) {
      OK <- FALSE
      w <- w + x
      print(w) # show every change
    }
    if (OK) break;
  }
  return(w)
}
```

```
m <- matrix( # only positive examples
c(c(1,1,1),c(1,1,-1),c(1,0,-1),
c(-1,1,1),c(-1,1,-1),c(-1,0,-1)),
nrow=6,byrow=TRUE)
```

Single-Layer Perceptron (SLP)**Generalization:**

Assumption: $x \in \mathbb{R}^n \Rightarrow \|x\| > 0$ for all $x \neq (0, \dots, 0)'$

as before: $w_{t+1} = w_t + (\delta + \varepsilon)x$ for $\varepsilon > 0$ (small) and $\delta = -w_t'x > 0$

$$\begin{aligned} \Rightarrow w'_{t+1}x &= \delta (\|x\|^2 - 1) + \varepsilon \|x\|^2 \\ &\quad \underbrace{}_{< 0 \text{ possible!}} \quad \underbrace{}_{> 0} \end{aligned}$$

Claim: Scaling of data does not alter classification task (if threshold 0)!

Let $\ell = \min \{ \|x\| : x \in B \} > 0$

Set $\hat{x} = \frac{x}{\ell}$ ⇒ set of scaled examples \hat{B}

$$\Rightarrow \|\hat{x}\| \geq 1 \Rightarrow \|\hat{x}\|^2 - 1 \geq 0 \Rightarrow w'_{t+1} \hat{x} > 0 \quad \checkmark$$

Theorem:

Let $X = P \cup N$ with $P \cap N = \emptyset$ be training patterns (P: positive; N: negative examples). Suppose training patterns are embedded in \mathbb{R}^{n+1} with threshold 0 and origin $0 \notin X$.

If separating hyperplane $H(w)$ exists,
then scaling of data does not alter classification task!

Proof:

Suppose $\exists x \in P \cup N$ with $\|x\| < 1$ and let $\ell = \min\{\|x\| : x \in P \cup N\} > 0$.

Set $\hat{x} = \frac{1}{\ell}x$ so that $\hat{P} = \{\frac{x}{\ell} : x \in P\}$ and $\hat{N} = \{\frac{x}{\ell} : x \in N\}$.

Suppose $\exists w$ with $\forall \hat{x} \in \hat{P} : w'\hat{x} > 0$ and $\forall \hat{x} \in \hat{N} : w'\hat{x} \leq 0$.

Then holds:

$$w'\hat{x} > 0 \Leftrightarrow w'\frac{x}{\ell} > 0 \Leftrightarrow w'x > 0$$

$$w'\hat{x} \leq 0 \Leftrightarrow w'\frac{x}{\ell} \leq 0 \Leftrightarrow w'x \leq 0$$

q.e.d.

as yet: *Online Learning*

→ Update of weights after each training pattern (if necessary)

now: *Batch Learning*

→ Update of weights only after test of all training patterns

→ Update rule:

$$w_{t+1} = w_t + \gamma \sum_{\substack{x \\ w_t' x < 0 \\ x \in B}} x \quad (\gamma > 0)$$

vague assessment in literature:

- advantage : „usually faster“

- disadvantage : „needs more memory“ ← just a single vector!

There exist numerous variants of Perceptron Learning Methods.

Theorem: (Duda & Hart 1973)

If rule for correcting weights is $w_{t+1} = w_t + \gamma_t x$ (i.e., if $w_t' x < 0$) and

$$1. \forall t \geq 0 : \gamma_t \geq 0$$

$$2. \sum_{t=0}^{\infty} \gamma_t = \infty$$

$$3. \lim_{m \rightarrow \infty} \frac{\sum_{t=0}^m \gamma_t^2}{\left(\sum_{t=0}^m \gamma_t\right)^2} = 0$$

then $w_t \rightarrow w^*$ for $t \rightarrow \infty$ with $\forall x: x'w^* > 0$. ■

e.g.: $\gamma_t = \gamma > 0$ or $\gamma_t = \gamma / (t+1)$ for $\gamma > 0$

as yet: *Online Learning*

→ Update of weights after each training pattern (if necessary)

now: *Batch Learning*

→ Update of weights only after test of all training patterns

→ Update rule:

$$w_{t+1} = w_t - \gamma \nabla f(w_t) \quad (\gamma > 0)$$

find weights by means of optimization

Let $F(w) = \{x \in B : w'x < 0\}$ be the set of patterns incorrectly classified by weight w .

Objective function: $f(w) = -\sum_{x \in F(w)} w'x \rightarrow \min!$

Optimum: $f(w) = 0$ iff $F(w)$ is empty

Possible approach: gradient method

$$w_{t+1} = w_t - \gamma \nabla f(w_t) \quad (\gamma > 0)$$

converges to a local minimum (dep. on w_0)

Gradient method

$$\mathbf{w}_{t+1} = \mathbf{w}_t - \gamma \nabla f(\mathbf{w}_t)$$

Gradient points in direction of steepest ascent of function $f(\cdot)$

$$\text{Gradient } \nabla f(\mathbf{w}) = \left(\frac{\partial f(\mathbf{w})}{\partial w_1}, \frac{\partial f(\mathbf{w})}{\partial w_2}, \dots, \frac{\partial f(\mathbf{w})}{\partial w_n} \right)$$

$$\frac{\partial f(\mathbf{w})}{\partial w_i} = -\frac{\partial}{\partial w_i} \sum_{x \in F(w)} \mathbf{w}' \mathbf{x} = -\frac{\partial}{\partial w_i} \sum_{x \in F(w)} \sum_{j=1}^n w_j \cdot x_j$$

$$= -\sum_{x \in F(w)} \underbrace{\frac{\partial}{\partial w_i} \left(\sum_{j=1}^n w_j \cdot x_j \right)}_{x_i} = -\sum_{x \in F(w)} x_i$$

Caution:
Indices i of w_i here denote components of vector \mathbf{w} ; they are **not** the iteration counters!

How difficult is it

- (a) to find a separating hyperplane, provided it exists?
- (b) to decide, that there is no separating hyperplane?

Let $B = P \cup \{-x : x \in N\}$ (only positive examples), $w_i \in \mathbb{R}$, $\theta \in \mathbb{R}$, $|B| = m$

For every example $x_i \in B$ should hold:

$$x_{i1} w_1 + x_{i2} w_2 + \dots + x_{in} w_n \geq \theta \quad \rightarrow \text{trivial solution } w_i = \theta = 0 \text{ to be excluded!}$$

Therefore additionally: $\eta \in \mathbb{R}$

$$x_{i1} w_1 + x_{i2} w_2 + \dots + x_{in} w_n - \theta - \eta \geq 0$$

Idea: η maximize \rightarrow if $\eta^* > 0$, then solution found

Gradient method

thus:

$$\text{gradient } \nabla f(\mathbf{w}) = \left(\frac{\partial f(\mathbf{w})}{\partial w_1}, \frac{\partial f(\mathbf{w})}{\partial w_2}, \dots, \frac{\partial f(\mathbf{w})}{\partial w_n} \right)'$$

$$= \left(-\sum_{x \in F(w)} x_1, -\sum_{x \in F(w)} x_2, \dots, -\sum_{x \in F(w)} x_n \right)'$$

$$= -\sum_{x \in F(w)} x$$

$$\Rightarrow \mathbf{w}_{t+1} = \mathbf{w}_t + \gamma \sum_{x \in F(w_t)} x$$

gradient method \Leftrightarrow batch learning

How difficult is it

- (a) to find a separating hyperplane, provided it exists?
- (b) to decide, that there is no separating hyperplane?

Let $B = P \cup \{-x : x \in N\}$ (only positive examples), $w_i \in \mathbb{R}$, $\theta \in \mathbb{R}$, $|B| = m$

For every example $x_i \in B$ should hold:

$$x_{i1} w_1 + x_{i2} w_2 + \dots + x_{in} w_n \geq \theta \quad \rightarrow \text{trivial solution } w_i = \theta = 0 \text{ to be excluded!}$$

Therefore additionally: $\eta \in \mathbb{R}$

$$x_{i1} w_1 + x_{i2} w_2 + \dots + x_{in} w_n - \theta - \eta \geq 0$$

Idea: η maximize \rightarrow if $\eta^* > 0$, then solution found

Matrix notation:

$$A = \begin{pmatrix} x'_1 & -1 & -1 \\ x'_2 & -1 & -1 \\ \vdots & \vdots & \vdots \\ x'_m & -1 & -1 \end{pmatrix} \quad z = \begin{pmatrix} w \\ \theta \\ \eta \end{pmatrix}$$

Linear Programming Problem:

$$f(z_1, z_2, \dots, z_n, z_{n+1}, z_{n+2}) = z_{n+2} \rightarrow \max!$$

$$\text{s.t. } Az \geq 0$$

} calculated by e.g. Kamarkar-algorithm in **polynomial time**

If $z_{n+2} = \eta > 0$, then weights and threshold are given by z .

Otherwise separating hyperplane does not exist!
