- Typical Fields of Application

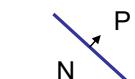

- Classification
- Prediction
- Function Approximation

Multi-Layer Perceptron (MLP)

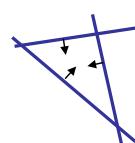

Lecture 11

What can be achieved by adding a layer?

- Single-layer perceptron (SLP)
⇒ Hyperplane separates space in two subspaces

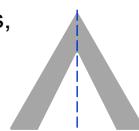

- Two-layer perceptron
⇒ arbitrary convex sets can be separated

connected by
AND gate in
2nd layer

- Three-layer perceptron
⇒ arbitrary sets can be partitioned into convex subsets,
convex subsets representable by 2nd layer,
resulting sets can be combined in 3rd layer

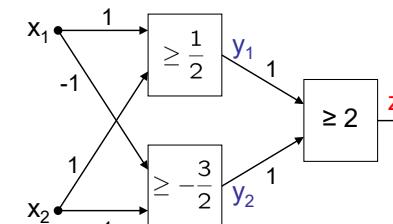

convex sets
of 2nd layer
connected by
OR gate in
3rd layer

⇒ more than 3 layers not necessary (in principle)

Multi-Layer Perceptron (MLP)

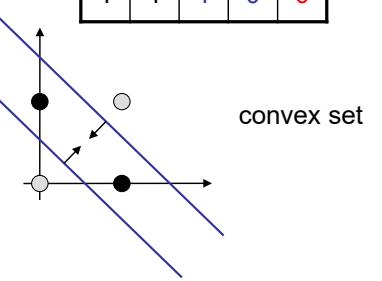

Lecture 11

XOR with 3 neurons in 2 steps

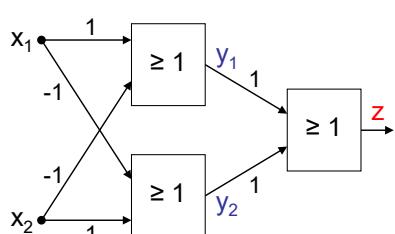

| x_1 | x_2 | y_1 | y_2 | z |
|-------|-------|-------|-------|-----|
| 0 | 0 | 0 | 1 | 0 |
| 0 | 1 | 1 | 1 | 1 |
| 1 | 0 | 1 | 1 | 1 |
| 1 | 1 | 1 | 0 | 0 |

$$\begin{aligned} x_1 + x_2 &\geq \frac{1}{2} \\ -x_1 - x_2 &\geq -\frac{3}{2} \end{aligned} \quad , \quad \begin{cases} x_2 \geq \frac{1}{2} - x_1 \\ x_2 \leq \frac{3}{2} - x_1 \end{cases}$$

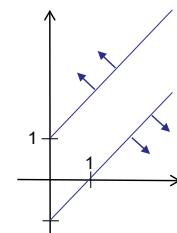

XOR with 3 neurons in 2 layers

| x ₁ | x ₂ | y ₁ | y ₂ | z |
|----------------|----------------|----------------|----------------|---|
| 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 1 | 1 |
| 1 | 0 | 1 | 0 | 1 |
| 1 | 1 | 0 | 0 | 0 |

without AND gate in 2nd layer

$$\begin{aligned} x_1 - x_2 \geq 1 \\ x_2 - x_1 \geq 1 \end{aligned} \quad , \quad \begin{cases} x_2 \leq x_1 - 1 \\ x_2 \geq x_1 + 1 \end{cases}$$

Evidently:

MLPs deployable for addressing significantly more difficult problems than SLPs!

But:

How can we adjust all these weights and thresholds?

Is there an efficient learning algorithm for MLPs?

History:

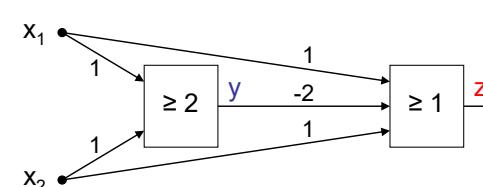

Unavailability of efficient learning algorithm for MLPs was a brake shoe ...

... until Rumelhart, Hinton and Williams (1986): Backpropagation

Actually proposed by Werbos (1974)

... but unknown to ANN researchers (was PhD thesis)

XOR can be realized with only 2 neurons!

| x ₁ | x ₂ | y | -2y | x ₁ -2y+x ₂ | z |
|----------------|----------------|---|-----|-----------------------------------|---|
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 1 | 1 |
| 1 | 0 | 0 | 0 | 1 | 1 |
| 1 | 1 | 1 | -2 | 0 | 0 |

BUT: this is not a layered network (no MLP) !

Quantification of classification error of MLP

- Total Sum Squared Error (TSSE)

$$f(w) = \sum_{x \in B} \|g(w; x) - g^*(x)\|^2$$

output of net
for weights w and input x target output of net
for input x

- Total Mean Squared Error (TMSE)

$$f(w) = \frac{1}{|B| \cdot \ell} \sum_{x \in B} \|g(w; x) - g^*(x)\|^2 = \frac{1}{|B| \cdot \ell} \cdot TSSE$$

training patters # output neurons const.
⇒ leads to same solution as TSSE

Learning algorithms for Multi-Layer-Perceptron (here: 2 layers)

idea: minimize error!

$$f(w_t, u_t) = \text{TSSE} \rightarrow \min!$$

Gradient method

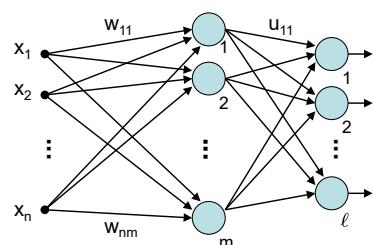

$$\begin{aligned} u_{t+1} &= u_t - \gamma \nabla_u f(w_t, u_t) \\ w_{t+1} &= w_t - \gamma \nabla_w f(w_t, u_t) \end{aligned}$$

BUT:

$f(w, u)$ cannot be differentiated!

Why? → Discontinuous activation function $a(\cdot)$ in neuron!

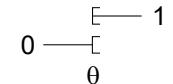

idea: find **smooth** activation function similar to original function !

$$a(x) = \begin{cases} 1 & \text{if } x \geq \theta \\ 0 & \text{otherwise} \end{cases}$$

Learning algorithms for Multi-Layer-Perceptron (here: 2 layers)

good idea: sigmoid activation function (instead of signum function)

- monotone increasing
- differentiable
- non-linear
- output $\in [0, 1]$ instead of $\in \{0, 1\}$
- threshold θ integrated in activation function

e.g.:

$$\left. \begin{aligned} a(x) &= \frac{1}{1 + e^{-x}} & a'(x) &= a(x)(1 - a(x)) \\ a(x) &= \tanh(x) & a'(x) &= (1 - a^2(x)) \end{aligned} \right\} \begin{array}{l} \text{values of derivatives directly} \\ \text{determinable from function} \\ \text{values} \end{array}$$

Learning algorithms for Multi-Layer-Perceptron (here: 2 layers)

Gradient method

$$f(w_t, u_t) = \text{TSSE}$$

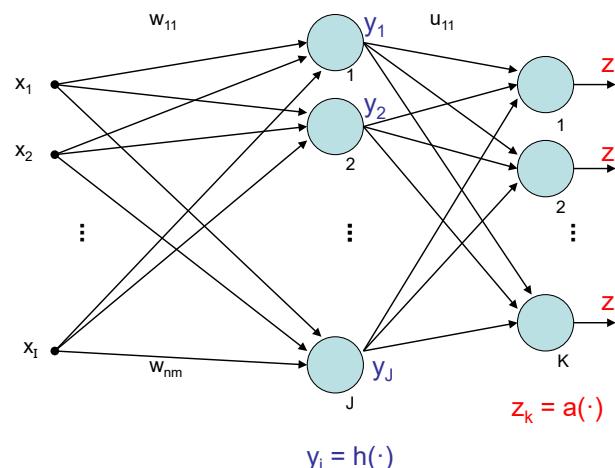

$$u_{t+1} = u_t - \gamma \nabla_u f(w_t, u_t)$$

$$w_{t+1} = w_t - \gamma \nabla_w f(w_t, u_t)$$

x_i : inputs

y_j : values after first layer

z_k : values after second layer

$$y_j = h \left(\sum_{i=1}^I w_{ij} \cdot x_i \right) = h(w'_j x)$$

output of neuron j
after 1st layer

$$z_k = a \left(\sum_{j=1}^J u_{jk} \cdot y_j \right) = a(u'_k y)$$

output of neuron k
after 2nd layer

$$= a \left(\sum_{j=1}^J u_{jk} \cdot h \left(\sum_{i=1}^I w_{ij} \cdot x_i \right) \right)$$

error of input x:

$$f(w, u; x) = \sum_{k=1}^K (z_k(x) - z_k^*(x))^2 = \sum_{k=1}^K (z_k - z_k^*)^2$$

↑
output of net

↑
target output for input x

error for input x and target output z^* :

$$f(w, u; x, z^*) = \sum_{k=1}^K \left[a \left(\underbrace{\sum_{j=1}^J u_{jk} \cdot h \left(\underbrace{\sum_{i=1}^I w_{ij} \cdot x_i}_{y_j} \right)}_{z_k} \right) - z_k^*(x) \right]^2$$

total error for all training patterns $(x, z^*) \in B$:

$$f(w, u) = \sum_{(x, z^*) \in B} f(w, u; x, z^*) \quad (\text{TSSE})$$

assume: $a(x) = \frac{1}{1 + e^{-x}} \Rightarrow \frac{da(x)}{dx} = a'(x) = a(x) \cdot (1 - a(x))$

and: $h(x) = a(x)$

chain rule of differential calculus:

$$[p(q(x))]' = \underbrace{p'(q(x))}_{\text{outer derivative}} \cdot \underbrace{q'(x)}_{\text{inner derivative}}$$

gradient of total error:

$$\nabla f(w, u) = \sum_{(x, z^*) \in B} \nabla f(w, u; x, z^*)$$

vector of partial derivatives w.r.t.
weights u_{jk} and w_{ij}

thus:

$$\frac{\partial f(w, u)}{\partial u_{jk}} = \sum_{(x, z^*) \in B} \frac{\partial f(w, u; x, z^*)}{\partial u_{jk}}$$

and

$$\frac{\partial f(w, u)}{\partial w_{ij}} = \sum_{(x, z^*) \in B} \frac{\partial f(w, u; x, z^*)}{\partial w_{ij}}$$

$$f(w, u; x, z^*) = \sum_{k=1}^K [a(u'_k y) - z_k^*]^2$$

partial derivative w.r.t. u_{jk} :

$$\begin{aligned} \frac{\partial f(w, u; x, z^*)}{\partial u_{jk}} &= 2 [a(u'_k y) - z_k^*] \cdot a'(u'_k y) \cdot y_j \\ &= 2 [a(u'_k y) - z_k^*] \cdot a(u'_k y) \cdot (1 - a(u'_k y)) \cdot y_j \\ &= 2 [z_k - z_k^*] \cdot z_k \cdot (1 - z_k) \cdot y_j \\ &\quad \underbrace{\qquad\qquad\qquad}_{\text{"error signal" } \delta_k} \end{aligned}$$

partial derivative w.r.t. w_{ij} :

$$\begin{aligned} \frac{\partial f(w, u; x, z^*)}{\partial w_{ij}} &= 2 \sum_{k=1}^K [a(u'_k y) - z_k^*] \cdot a'(u'_k y) \cdot u_{jk} \cdot h'(w'_j x) \cdot x_i \\ &\quad z_k \quad z_k(1-z_k) \quad y_j(1-y_j) \\ &= 2 \cdot \sum_{k=1}^K [z_k - z_k^*] \cdot z_k \cdot (1-z_k) \cdot u_{jk} \cdot y_j(1-y_j) \cdot x_i \\ &\quad \text{factors reordered} \quad \curvearrowleft \\ &= x_i \cdot y_j \cdot (1-y_j) \cdot \sum_{k=1}^K 2 \cdot [z_k - z_k^*] \cdot z_k \cdot (1-z_k) \cdot u_{jk} \\ &\quad \underbrace{\qquad\qquad\qquad}_{\text{error signal } \delta_k \text{ from previous layer}} \\ &\quad \underbrace{\qquad\qquad\qquad}_{\text{error signal } \delta_j \text{ from "current" layer}} \end{aligned}$$

error signal of neuron in inner layer determined by

- error signals of all neurons of subsequent layer and
- weights of associated connections.

↓

- First determine error signals of output neurons,
- use these error signals to calculate the error signals of the preceding layer,
- use these error signals to calculate the error signals of the preceding layer,
- and so forth until reaching the first inner layer.

↓

thus, error is propagated backwards from output layer to first inner layer
 ⇒ **backpropagation** (of error)

Generalization (> 2 layers)

Let neural network have L layers S_1, S_2, \dots, S_L .

Let neurons of all layers be numbered from 1 to N.

All weights w_{ij} are gathered in weights matrix W.

Let o_j be output of neuron j.

$j \in S_m \rightarrow$
neuron j is in
m-th layer

error signal:

$$\delta_j = \begin{cases} o_j \cdot (1 - o_j) \cdot (o_j - z_j^*) & \text{if } j \in S_L \text{ (output neuron)} \\ o_j \cdot (1 - o_j) \cdot \sum_{k \in S_{m+1}} \delta_k \cdot w_{jk} & \text{if } j \in S_m \text{ and } m < L \end{cases}$$

correction:

$$w_{ij}^{(t+1)} = w_{ij}^{(t)} - \gamma \cdot o_i \cdot \delta_j \quad \begin{array}{l} \text{in case of online learning:} \\ \text{correction after each test pattern presented} \end{array}$$

⇒ other optimization algorithms deployable!

in addition to **backpropagation** (gradient descent) also:

• **Backpropagation with Momentum**

take into account also previous change of weights:

$$\Delta w_{ij}^{(t)} = -\gamma_1 \cdot o_i \cdot \delta_j - \gamma_2 \cdot \Delta w_{ij}^{(t-1)}$$

• **QuickProp**

assumption: error function can be approximated locally by quadratic function,
 update rule uses last two weights at step t-1 and t-2.

• **Resilient Propagation (RPROP)**

exploits sign of partial derivatives:

2 times negative or positive → increase step size!

change of sign → reset last step and decrease step size!

typical values: factor for decreasing 0,5 / factor for increasing 1,2

• **Evolutionary Algorithms**

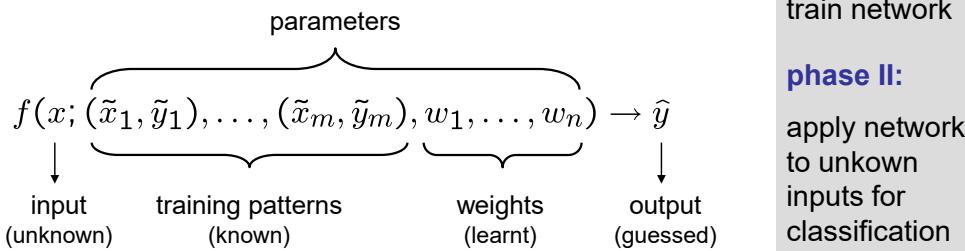

individual = weights matrix

Classification

given: set of training patterns (input / output)

$$\tilde{x}_i \quad \tilde{y}_i$$

output = label
(e.g. class A, class B, ...)

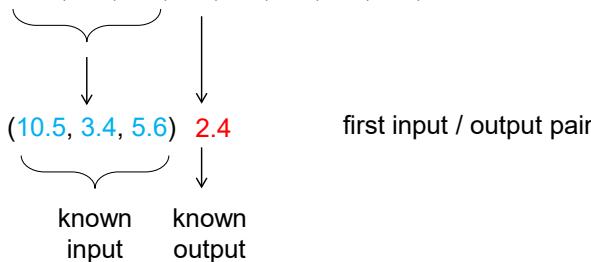

- phase I:**
train network
- phase II:**
apply network to unknown inputs for classification

Prediction of Time Series: Example for Creating Training Data

given: time series 10.5, 3.4, 5.6, 2.4, 5.9, 8.4, 3.9, 4.4, 1.7

time window: k=3

further input / output pairs: (3.4, 5.6, 2.4)

(5.6, 2.4, 5.9)

(2.4, 5.9, 8.4)

(5.9, 8.4, 3.9)

(8.4, 3.9, 4.4)

5.9

8.4

3.9

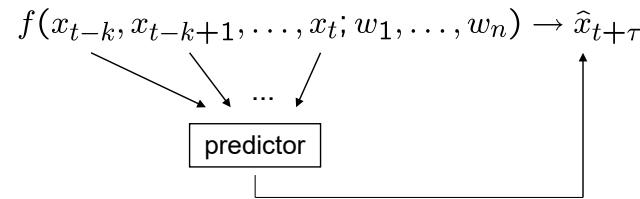

4.4

1.7

Prediction of Time Series

time series x_1, x_2, x_3, \dots (e.g. temperatures, exchange rates, ...)

task: given a subset of historical data, predict the future

- phase I:**
train network
- phase II:**
apply network to historical inputs for predicting unkown outputs

Function Approximation (the general case)

task: given training patterns (input / output), approximate unkown function

→ should give outputs close to true unkown function for arbitrary inputs

- values between training patterns are **interpolated**
- values outside convex hull of training patterns are **extrapolated**
